GORENIETIH IDEALS OF HEIGHT 3

David A. Buchsbaum and David Eisenbud

PREFACE

This paper is an early version of "Algebra structures for finite free resolutions, and some structure theorems for ideals of codimension 3" that appeared in the American Journal of Mathematics (99). The work was actually done in the spring of 1973. The printed version is considerably more complete; so the reader may well ask why this preliminary version should now appear.

The main theorem in this paper is quite simple: Gorenstein ideals of height 3 are always generated by Pfaffians of a suitable matrix. In this form, it has had reasonably wide application, mostly in providing a convenient class of examples on which conjectures could be formulated or checked. But the proof given in our final version was based on technical multilinear algebra of a sort which is unpleasant to read, whereas, in this early version, the technique was suppressed to a certain extent to allow us to give a more relaxed exposition.

Several people who liked the naive approach of this early version have suggested that it should, finally, appear too, and these notes seem a plausible format in which that can happen.

Several people have done further work related to this paper that seems to us quite significant. Among these, Avramov has shown that there is a real obstruction to the associativity of the algebra structure on a resolution [Am. J. Math. 103 (1981) 1-37] and Kustin and Miller have shown that it vanishes for resolutions of Gorenstein ideals of codimension 4 [Math. Z. 173 (1980) 171-184], and, in a series of preprints, have worked out a piece of the corresponding structure theory for codimension 4 Gorenstein ideals.

Received February 1, 1982

Both authors were partially supported by the NSF during the preparation of this paper.
§2. Introduction

In [SER, Prop 3], Serre proved that if \( R \) is a regular local ring, and if \( I \) is an ideal of \( R \) of height 2 such that \( R/I \) is Gorenstein, then \( I \) can be generated by two elements. Serre also remarked that the corresponding statement for height 3 ideals is false. The purpose of this paper is to prove the structure theorem that does hold for the Gorenstein ideals of height 3, namely that these ideals are characterized as the ideals of Pfaffians of certain alternating matrices (Theorem 4; see below for definitions). From this it follows, for example, that the minimal number of generators of such an ideal must be odd. Fundamental to our proof is the fact that a minimal free resolution of any cyclic \( R \)-module can be equipped with the structure of a (not necessarily associative) graded commutative algebra.

Our structure theorem is modelled on the theorem of Hilbert that characterizes the ideals \( I \) of height 2 in a regular local ring \( R \) such that \( R/I \) is Macaulay, as the ideals generated by the \( n \times (n-1) \) minors of certain matrices. In its modern form, this theorem actually shows that ideals of homological dimension 1 in any noetherian ring can be similarly characterized [Ref. HIL, BUR, B-E 3]. (The same proofs also yield a global version; the result is generally known by the slogan "Macaulay subschemes of codimension 2 of a smooth scheme are determinantal", and attributed variously.) Like the result of Hilbert, our structure theorem admits an extension to all local rings, which we will describe below, though we have not been able to globalize it.

We will follow Bourbaki's terminology in saying that the height of an ideal \( I \) of a noetherian ring \( R \) is the minimum of the dimensions of the local rings \( R_P \), where \( P \) runs through the prime ideals containing \( I \). The grade of \( I \) is the length of a maximal \( R \)-sequence contained in \( I \) (Bourbaki calls this the
I-depth of \( R \).  

We will say that the ideal \( I \) in the local noetherian ring \( R \) is Gorenstein of grade \( k \) if 

a) grade \( I = k = \text{hd} \, R/I \) (where \( \text{hd} \) denotes homological dimension), 

b) \( \text{Ext}_R^k (R/I, R) \cong R/I. \)

As is easily seen, this is equivalent to the requirement that the minimal free resolution of \( R/I \) have the form 

\[ \mathbb{Z}^0 \rightarrow R \xrightarrow{\phi_2} R_{k-1} \rightarrow \cdots \rightarrow R_1 \rightarrow R \] 

and that \( R^* = \text{Hom}_R(R, R) \) be a resolution of \( \text{Coker}(\phi_k) \). It is a theorem of Serre's (BRAS, TH. 5.1) that an ideal \( I \) of a regular local ring \( R \) is Gorenstein in this sense if and only if the factor ring \( R/I \) is a Gorenstein ring. Our structure theorem actually characterizes the Gorenstein ideals of grade 3 in any local ring.

The structure of Gorenstein ideals of grade \( \geq 4 \) remains a mystery. Of course, any complete intersection - that is, any ideal \( I \) which can be generated by (grade 1) elements - is Gorenstein. It is known \([S-E 2 \text{ and KUN}]\) that a Gorenstein ideal of grade \( k \) in a local ring cannot be minimally generated by \( k + 1 \) elements.

As was mentioned above, our structure theorem implies that any Gorenstein ideal of grade 3 has an odd number of generators. It is easy to show, using that theorem, that every odd number \( 2n + 1 \geq 3 \) is actually achieved (see Section 5). It follows that for any \( k \) and \( n \geq 0 \) there are Gorenstein ideals of depth \( k \) that are minimally generated by \( k + 2n \) \((n \geq 0)\) generators.

It is known that if \( \phi \) is a square \( n \times n \) matrix of indeterminates, then the ideal generated by the \( p \times p \) minors of \( \phi \) is a Gorenstein ideal of grade \((n - p + 1)^2\), minimally generated by \( \binom{n}{p}^2 \) elements \([S-R]\) for \( p = n - 1 \), \([SVA]\) in general.)
Thus, for example, it is known that the minimum number of generators of a Gorenstein ideal of grade 4 may be any even number \( \geq 4 \), or any perfect square. 5 is known to be impossible, but there are examples, due to Hochster, Kunz and Herzog, with 7, 11 and 13 generators. It seems reasonable to guess that there should be Gorenstein ideals of grade 4 minimally generated by any number of generators \( \geq 6 \).

The structure theorem presented here can be used to "lift" (in the sense of Grothendieck's lifting problem - see [B-E-O]) four generator ideals of height 3 in a 3-dimensional Gorenstein ring and Gorenstein ideals of grade 3 in any ring.

We will now describe the contents of this paper.

In the first section we show that any free resolution of a cyclic module has a graded commutative algebra structure, for which the differential of the resolution is a derivation (the algebra is only homotopy-associative), and we deduce the fact we will need about the algebra structure on a resolution of a Gorenstein ideal.

"multiplication into the top degree" induces an isomorphism between the resolution and its dual. Sections 2 and 3 review the tools needed for the main theorem, and contain no proofs. Section 2 is devoted to a criterion for the exactness of a complex [B-E 1], while Section 3 is devoted to some facts about linear algebra which were probably familiar to Cayley [CAY].

The fourth section is devoted to the structure theorem itself. The theorem is applied in Section 5 to give two classes of examples of Gorenstein ideals of height 3.

We wish to express our thanks to S. MacLane, who clarified the material in Section 1 for us.

We have recently learned that Watanabe [WAT] has independently proved that Gorenstein ideals of grade three are minimally generated by an odd number of elements, and conjectured that this pheno-
menon should be connected with skew-symmetry, as we have shown.

§1. Commutative algebra structures on resolutions

Let $R$ be a commutative ring, and let $P_d \ldots P_2 \rightarrow P_1 \rightarrow R$
be a projective resolution, with $P_0 = R$. We define the symmetric
square $S_2(P)$ to be

$$S_2(P) = \frac{(P \otimes P)}{M}$$

where $M$ is the graded submodule of $P \otimes P$ generated by

$$\{ f \otimes g - (-1)^{\deg f \deg g} g \otimes f | f, g \text{ homogeneous elements of } P \}.$$  

Of course $P \otimes P$ is not only a graded module, it is a complex
with differential

$$d(f \otimes g) = df \otimes g - (-1)^{\deg f} f \otimes dg.$$  

It is easy to check that $d(M) \subseteq M$, so $S_2(P)$ inherits the structure
of a complex from $P \otimes P$. Moreover, each component of $S_2(P)$
is a projective $R$-module since for each $k$ we have

$$S_2(P)_k \cong \bigoplus_{1 \leq i \leq j \leq k} P_i \otimes P_j + T_k$$

where

$$T_k = \begin{cases} 0 & \text{if } k \text{ is odd}, \\ 2 & \text{if } k \text{ is of the form } 4n + 2, \\ S_2(P_{k/2}) & \text{if } k \text{ is of the form } 4n. \end{cases}$$

Thus $S_2(P)$ is a complex of projective $R$-modules, and is isomorphic
to $P$ in degrees 0 and 1. By the comparison theorem for
projective complexes, there exists a map of complexes $S_2(P) \rightarrow P$
which extends the equality in degrees 0 and 1, and the map $\phi$
clearly be chosen so that the restriction of $\phi$ to
F_0 \otimes F_k = R \otimes F_k \subseteq S_2(F)_k \text{ is the canonical isomorphism }

R \otimes F_k \to F_k. \text{ If we write } f \cdot g = \phi(f \otimes g), \text{ where } f, g \in F, \text{ and }

\overline{f \otimes g} \text{ is the image, in } S_2(F), \text{ of } f \otimes g, \text{ then the conditions that the map }

\text{must satisfy are easily seen to be equivalent to the statement that } 
\text{ \cdot \ makes } F \text{ into a (non-associative) graded commutative differential algebra, with differential } d, \text{ and with structure map } R \to F \text{ given by the inclusion into degree 0. Furthermore, it follows from the homotopy uniqueness of } \phi \text{ that this algebra is homotopy associative. If } F_i = 0 \text{ for } i \geq 4, \text{ it is easily seen that } F \text{ is actually associative.}

\text{We now specialize, and suppose that } R \text{ is a local noetherian ring, that } I \text{ is a Gorenstein ideal of } R \text{ of depth } n, \text{ and that }

\begin{array}{c}
\begin{array}{c}
\varepsilon : 0 \to F_n \\
\varepsilon : F_{n-1} \to F_n \\
\vdots \\
\varepsilon : R \\
\end{array}
\end{array}

\text{is a minimal free resolution of } R/I, \text{ equipped with a multiplication } \cdot : F \otimes F \to F, \text{ as above. Since } I \text{ is Gorenstein, we may make the identification } F_n = R, \text{ so that, for each } k \leq n, \text{ the map } \cdot : F_k \otimes F_{n-k} \to F_n = R \text{ induces a map }

s_k : F_k \to F_{n-k}.

\textbf{Theorem 1}: \text{ For each } k \leq n, \text{ } s_k \text{ is an isomorphism.}

\textbf{Remark}: \text{ Let } K \text{ be the residue field of } R. \text{ The multiplication we have defined on } F \text{ induces the usual algebra structure on Tor}_k^R(R/I, K). \text{ Thus our theorem extends the result of } [A-G] \text{ who proved that if } R \text{ is regular, and } R/I \text{ is Gorenstein, then Tor}_k^R(R/I, K) \text{ is a "Poincaré algebra" - that is, the pairings }

\text{Tor}_k^R(R/I, K) \otimes \text{Tor}_{n-k}^R(R/I, K) \to \text{Tor}_n^R(R/I, K)
are perfect (where $n = \text{depth } I = \text{hd}_R R/I$). Of course, if $R$ is regular, our theorem can be deduced immediately from this one, but our proof is considerably simpler.

**Proof of Theorem 1**: We claim that the following diagram commutes up to sign:

For, if $f \in P_k$, $g \in P_{n-k+1}$, then $f \cdot g \in P_{n+1} = 0$, so

$$0 = d_{n+1}(f \cdot g) = d_k(f) \cdot g + (-1)^{|f|} d_{n-k+1}(g),$$

or $d_k(f) \cdot g = \pm f \cdot d_{n-k+1}(g)$.

Consequently,

$$s_{k-1}d_k(f)(g) = d_k(f) \cdot g$$

$$= \pm f \cdot d_{n-k+1}(g)$$

$$= s_k(f)(d_{n-k+1}(g))$$

$$= d_n^*(s_k(f))(g).$$

Thus $s_{k-1}d_k = \pm d_{n-k+1}^*s_k$, as required.

Now, since $I$ is Gorenstein, both $P$ and $P^*$ are minimal free resolutions of $R/I$ and it follows that any map of complexes $P \to P^*$ which extends an isomorphism in degree 0 must be an isomorphism. Thus each $s_k$ is an isomorphism.
§2. How to prove that a complex is exact

The proof of our main theorem on Gorenstein rings hinges on showing that a certain complex constructed from an alternating matrix is exact. In this section we will review the technique that we will use to prove this exactness, and state one further necessary result on complexes.

Let \( R \) be any commutative ring, and suppose \( f : A \rightarrow B \) is a map of \( R \)-modules. We define the rank of \( f \) to be the largest integer \( k \) such that the \( k \)th exterior power \( \Lambda^k f \neq 0 \). For any integer \( j \geq 0 \), the map \( \Lambda^j f : \Lambda^j A \rightarrow \Lambda^j B \) induces a map \( \Lambda^j A \times (\Lambda^j B)^* \rightarrow R \), where \( * \) denotes \( \text{Hom}_R(\_, R) \), as usual. We will associate to \( f \) an ideal \( I(f) \subseteq R \) by defining

\[
I(f) = \text{Image}(\Lambda^k A \times (\Lambda^k B)^* \rightarrow R) \quad \text{for} \quad k = \text{rank} \; f.
\]

If \( A \) and \( B \) are free modules with given bases, and \( f \) corresponds to a matrix \( \phi \), then rank \( f \) is just the size of the largest nonvanishing minor of \( \phi \), and \( I(f) \) is the ideal generated by all the \( (\text{rank} f) \times (\text{rank}(f)) \) minors of \( \phi \). (\( I(f) \) may thus be viewed as the smallest non-zero Fitting ideal of \( \text{Coker} \; f \).)

If \( I \) is an ideal of \( R \), we will write \( \sqrt{I} \) for the radical of \( I \).

Now let \( R \) be a noetherian ring, and let

\[(N) \quad 0 \rightarrow F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_1 \rightarrow F_0 \]

be a complex of finitely generated free \( R \)-modules. In this paper, we will use the following two results:

**Theorem 2.1.** The complex \((N)\) is exact if and only if, for all \( k \geq 1 \),
1) rank $f_k + \text{rank } f_{k+1} = \text{rank } f_k$ and

2) grade $\sqrt{I(f_k)} \geq k$.

**Proposition 2.2.** Suppose (*) is exact. Then for each $k$,

$$\sqrt{I(f_{k+1})} \supseteq \sqrt{I(f_k)}.$$ 

Theorem 2.1 is a special case of the main theorem of [B-E-1], and Proposition 2.2 occurs as Theorem 2.1 a) in [B-E-2].

§1. A little linear algebra

In this section we will briefly review the results on Pfaffians that we will need. For a modern, basis-free treatment of these matters, which also works for projective modules, see [B-E-4]. An exposition which uses bases, but which contains more, may be found in [HEY].

Let $R$ be a commutative ring, and let $F$ be a finitely generated free $R$-module. A map $f: F \to F^\times$ is said to be alternating if with respect to some (and therefore with respect to any) basis and dual basis of $F$ and $F^\times$, the matrix of $f$ is skew-symmetric, and all its diagonal elements are 0.

Choose a basis of $F$, and identify $f$ and the matrix of $f$ with respect to the chosen basis of $F$ and the dual basis of $F^\times$. Suppose $f$ is alternating. Then

3.1) If $\text{rk } F = n$ is even, there exists an element $\text{Pf}(f) \in R$, called the Pfaffian of $f$, which is a polynomial function of the entries of $f$, such that $\det(f) = (\text{Pf}(f))^2$.

Let $f_{ij}$ be the $(i,j)^{\text{th}}$ entry of $f$ with respect to the chosen bases. For $1 \leq i \neq j \leq n$, let $f_{ij}$ be the matrix obtained from $f$ by deleting the $i$th and $j$th rows and columns. Suppose that $n$ is even. Then for any $i, 1 \leq i \leq n$, the Pfaffian of $f$ can be compu-
3.2) \[ \text{Pf}(f) = \sum_{i \neq j} (-1)^{ij} \phi_{ij} \text{Pf}(e_{ij}), \]

(see [BOU, Exer. 5, p. 86]).

Given any free summand \( G \) of \( F \), generated by an even number \( 2k \) of the basis elements \( e_i \) of \( F \), we say that the Pfaffian of the composite map

\[
G \xrightarrow{\text{incl.}} f \xrightarrow{\text{incl.}^*} F \xrightarrow{\phi} F^* \xrightarrow{\text{incl.}^*} G^*
\]

is "a Pfaffian of \( f \) of order \( 2k \)." We denote by \( \text{Pf}_{2k}(f) \) the ideal of \( R \) which is generated by all the Pfaffians of \( f \) of order \( 2k \). If \( 2k > n \), we set \( \text{Pf}_{2k}(f) = 0 \). We will denote by \( I_k(f) \) the ideal of \( R \) generated by all the minors of \( f \) of order \( t \).

We now have, for each \( k \),

\[
\begin{cases}
I_{2k-1}(f) \subseteq \text{Pf}_{2k}(f), \\
\text{Pf}_{2k}(f) \supseteq I_{2k}(f) \cap (\text{Pf}_{2k}(f))^N \text{ where } N = \binom{2k}{2} + 1.
\end{cases}
\]

**Remark:** There are in fact more precise formulae which express the minors of \( f \) in terms of Pfaffians of \( f \). See [B-E-4] or [HEY] for details.

3.4) It follows from 3.3) that if \( f \) is alternating, and \( \text{rk } f = 2k-1 \) is an odd number, then \( I(f) = I_{2k-1}(f) \) is nilpotent.

Now suppose that \( n \) is odd. Then we have

3.5) \( \text{rk}(f) \leq n - 1 \) and \( I_{n-1}(f) = (\text{Pf}_{n-1}(f))^2 \).
§4. The Structure Theorem

Throughout this section, $R$ will denote a noetherian local ring with maximal ideal $J$.

Theorem 4. 1) Let $n \geq 3$ be an odd integer, and let $F$ be a free $R$-module of rank $n$. Let $f:F \to F^\vee$ be an alternating map of rank $n-1$ whose image is contained in $JF^\vee$. If $F_{n-1}(f)$ has grade 3, then $F_{n-1}(f)$ is Gorenstein, and the minimal number of generators of $F_{n-1}(f)$ is $n$.

2) Every Gorenstein ideal of $R$ of grade 3 arises as in 1).

Corollary: The minimal number of generators of a Gorenstein ideal of grade 3 is odd.

Proof: This follows from part 2) of the theorem, since only odd $n$ are considered in part 1).

Remarks: 1) In the proof of part 1), we will construct a complex whose existence shows that if $F$ is a free module of odd rank $n$, and $f:F \to F^\vee$ is an alternating map of rank $n-1$, then

$$\text{grade } (F_{n-1}(f)) \leq 3.$$ 

2) One further question that can be raised in connection with Theorem 4 is the uniqueness question: what can be said about two maps $f$ and $f'$, both satisfying the conditions of part 1) of the theorem, and having

$$F_{n-1}(f) = F_{n-1}(f')?$$

In case $R$ is complete and 2 is a unit in $R$, the most desirable conclusion holds: there exists an automorphism $a:F \to F$ such that

$$f' = a^nf.$$
If $\mathbb{R}$ is not complete, we have not been able to show the existence of such an $a$; but neither have we been able to find a counterexample.

**Proof:** 1) Choose a basis for $F$, a dual basis for $F^\times$, and let $\phi$ be the matrix of $F$ with respect to these bases. Let $\gamma^1_1$ be the Pfaffian of the alternating matrix obtained from $\phi$ by deleting the $i$th row and the $i$th column, and let $grR \to F$ be the map whose matrix, in terms of the given basis of $F$ is

$$
\gamma = \begin{pmatrix}
\gamma^1_1 \\
\gamma^2_2 \\
\gamma^3_3 \\
\vdots \\
\gamma^n_n
\end{pmatrix}
$$

Then, by virtue of the formula for the expansion of Pfaffians along a row (i.e., formula 3.2), the $i$th coefficient of $\phi^\times$ is the Pfaffian of the $n+1$ by $n+1$ matrix obtained from $\phi$ by repeating the $i$th row and the $i$th column; thus $\phi^{\times} = 0$.

Since $\phi^\times = -\phi$, we also have

$$
\gamma^\times = -\gamma^\times \phi^{\times} = - (\phi^\times)^\times = 0
$$

so that

$$
(\star) \quad 0 \to_R g \to_F f \to_{g^\times} g^{\times} \to_R
$$

is a complex. We will prove that this complex is exact. Since Coker $g^\times = R/(Pf_{n-1}(f))$, this will show that $Pf_{n-1}(f)$ is a Gorenstein ideal.

To prove that $(\star)$ is exact, we invoke Theorem 2.1. The condition on the ranks of the maps is easily checked. For we have assumed
that \( \text{rank } f = n - 1 \), and by 3.5) the square of the ideal generated by the entries of \( \gamma' \) is \( I_{n-1}(f) \neq 0 \), so \( \text{rank } g = 1 \).

To check the second condition of Theorem 2.1 is even easier. For we have \( I(g) = I(g) = P_{n-1}(f) \), and \( I(f) = (P_{n-1}(f))^2 \), which has the same grade as \( P_{n-1}(f) \). Since we have assumed that \( P_{n-1}(f) \) has grade 3, condition 2 of Theorem 2.1 is also satisfied, so that \((^*\text{M})\) is exact.

2) Next, suppose that \( I \) is a Gorenstein ideal of grade 3, and let

\[
(\star \text{M}) \quad 0 \rightarrow P_3 \xrightarrow{f_3} P_2 \xrightarrow{f_2} P_1 \rightarrow R \rightarrow R/I \rightarrow 0
\]

be a minimal free resolution of \( R/I \). We have seen in Section 1 that \((\star \text{M})\) has the structure of a differential graded commutative algebra. By Theorem 1 the multiplication in this algebra gives a perfect pairing \( P_2 \otimes P_1 \rightarrow P_3 \). If we identify \( P_3 \) and \( R \), then this pairing yields an identification of \( P_1 \) with \( P_2 \). We will show that with respect to this identification, \( f_2 \) is alternating.

Let \( \{e_i\}_{i=1}^n \) be a basis of \( P_2 \), and let \( \{\xi_1\}_{i=1}^n \) be the dual basis of \( P_2 \). Let \( \phi = \{\phi_{ij}\} \) be the matrix of \( f_2 \) with respect to the basis \( \{e_i\} \) and \( \{\xi_i\} \). We want to show that \( \phi_{ij} = - \phi_{ji} \) and that \( \phi_{ii} = 0 \). But \( \phi_{ij} = (f_2(e_j))(e_i) \), where we regard \( f_2(e_j) \) as a functional on \( P_2 \). Of course, we may regard this last term as a product with respect to the algebra structure of \((\star \text{M})\) and write

\[ \phi_{ij} = (f_2(e_j)) \cdot e_i \in P_3 = R. \]

Applying \( f_3 \), and using the formula for the differentiation of a product, we get

\[ f_3(\phi_{ij}) = f_1 f_2(e_j) \cdot e_i + f_2(e_j) \cdot f_2(e_i) = f_2(e_j) \cdot f_2(e_i), \]

42
since \( f_1^2 = 0 \). But we know from Section 1 that the product in (\( ^m \)) is strictly skew-commutative. Since \( f_2(e_1) \) and \( f_2(e_1) \) both have degree 1, we see that
\[
f_3(\phi_{ij}) = -f_3(\phi_{ji}) \quad \text{and} \quad f_3(\phi_{ij}) = 0.
\]

Since \( f_3 \) is a monomorphism, it follows that
\[
\phi_{ij} = -\phi_{ji} \quad \text{and} \quad \phi_{ii} = 0.
\]

Thus \( f_2 \) is alternating.

We now show that \( \text{Pr}_{n-1}(f_2) = I \). First of all, we have rank \( f_2 = n - 1 \) by Theorem 2.1, and depth \( I(f_2) \geq 3 \) by Proposition 2.2. Consequently, if we view \( f_2 \) as a map from \( \mathbb{F}_2 \) to \( \mathbb{F}_1 = \mathbb{F}_2^* \), then \( f_2 \) will satisfy all the conditions of the first part of the theorem. As in the proof of the first part of the theorem, we can construct a map \( g: R \to \mathbb{F}_2 \) so that
\[
0 \to R \overset{g}{\to} \mathbb{F}_2 \overset{f_2}{\to} \mathbb{F}_2^* \overset{g^*}{\to} R
\]
is exact, and so that \( I(g) = \text{Pr}_{n-1}(f) \). Since both \( g \) and \( f_1^* \) are kernels of \( f_2^* = f_2 \), we see that there must exist a unit \( u \in R \) such that \( f_1^* = g_1^* \), \( f_1^* = ug^* \), and \( I = \text{Pr}_{n-1}(f) \). This concludes the proof.

§5. Some examples of Gorenstein ideals

a) Generic Gorenstein ideals of height 1.

Let \( k \) be a commutative ring, and let \( G_n(k) \) be a generic alternating \((2n + 1) \times (2n + 1)\) matrix over \( k[\{x_{ij}\}_{1 \leq i < j \leq 2n+1}] = R_n(k); \)
Proposition 5.1. Let $k$ be a field. For every $n \geq 1$, Pfaffian $(G_n(k))$ is a Gorenstein ideal of height $3$ in $R_n(k)$, so that $R_n(k)/Pf_{2n}(G_n(k))$ is a Gorenstein ring. Moreover, $R_n(k)/Pf_{2n}(G_n(k))$ is a normal domain, non-singular in codimension $6$.

Proof. By 3.5) and the fact that $G_n(k)$ is "generic", we have rank $G_n(k) = 2n$. Thus part 1 of Theorem 4 shows that $Pf_{2n}(G_n(k))$ is a Gorenstein ideal if it has grade $3$. Since $R_n(k)$ is a Macaulay ring, grade $(Pf_{2n}(G_n(k))) = \text{height } (Pf_{2n}(G_n(k)))$. However, it is known [H00, p. 196] that

$$\text{height } (Pf_{2n-2\ell}(G_n(k))) = (\ell + 1)(2\ell + 3).$$

In particular, height $(Pf_{2n}(G_n(k))) = 3$. Thus we have the first assertion of Proposition 5.1.

To prove that $S = R_n(k)/Pf_{2n}(G_n(k))$ is a normal domain, we will use the Krull-Serre characterization [MAT, Th. 39] and verify the criteria $S_2$ and $R_1$. Since $S$ is Gorenstein and thus, in particular, Macaulay, we need only show that $R_1$ holds for $S$; that is, that every localization of $S$ at a prime of height $1$ is regular. What we will actually see is that if $P$ is any prime not containing $I = Pf_{2n-2}(G_n(k))/Pf_{2n}(G_n(k))$, then $S_P$ is regular.
Since \( \text{height } (\text{Pf}_{2n-2}(G_n(k))) = 10 \), the height of \( I \) is 7 so this will show that \( S \) is non-singular in codimension 6 as well.

Let \( A \) be any \((2n - 2) \times (2n - 2)\) Pfaffian of \( G_n(k) \) and let \( \mathfrak{U} \) be the multiplicatively closed set generated by \( A \). It is not difficult to see that \( R_n(k)_{\mathfrak{U}}/\text{Pf}_{2n}(G_n(k)) \) is isomorphic to \( R_n(k)_{\mathfrak{U}}/\text{Pf}_2(G_1(k)) \). For, assume that \( A \) is the \((2n - 2) \times (2n - 2)\) Pfaffian of the submatrix of \( G_n(k) \) obtained by omitting the first three columns and rows. Since \( A \) is invertible in \( R_n(k)_{\mathfrak{U}} \), \( G_n(k) \) may be transformed over \( R_n(k)_{\mathfrak{U}} \) to

\[
\begin{pmatrix}
0 & y_{12} & y_{13} \\
-y_{12} & 0 & y_{23} \\
-y_{13} & -y_{23} & 0 \\
0 & 1 & -1 & 0
\end{pmatrix}
\]

where the \( y_{ij} \) are polynomials of the form

\[
y_{ij} = x_{ij} + \text{(higher order terms)}.
\]

We therefore see that \( R_n(k)_{\mathfrak{U}}/\text{Pf}_{2n}(G_n(k)) \) is a localization of a polynomial ring. Thus if \( P \) is a prime of \( S \) not containing all the Pfaffians of order \( 2n - 2 \) of \( G_n(k) \), then one of these Pfaffians is invertible in \( S_P \) so that \( S_P \) is a localization of a regular ring. This shows that \( S \) is a normal ring.

Since \( \text{Pf}_{2n}(G_n(k)) \) is a homogeneous ideal, \( \text{Spec } S \) is connected, so \( S \) is a normal domain, non-singular in codimension 6.

b) As was mentioned in the introduction, this investigation began from a desire to know about the Gorenstein ideals of height \((= \text{depth}) 3 \) in regular local rings. In particular, we may
consider rings of the form \( k[[x,y,z]] \), where \( k \) is a field and \( x, y, z \) are indeterminates. By part 2) of Theorem 4.1, any depth 3 Gorenstein ideal in this ring must have an odd number of generators.

Let \( n \geq 3 \) be odd, and let \( R = k[[x,y,z]] \). Let \( H_n \) be the \( n \times n \) matrix of the form:

\[
H_n =
\begin{pmatrix}
0 & x & 0 & \ldots & \ldots & \ldots & 0 & z \\
-x & 0 & y & \ldots & \ldots & \ldots & z & 0 \\
0 & -y & 0 & \ddots & & \ddots & \ddots & \\
\ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \\
\ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & 0 & x \\
0 & -z & -x & 0 & y & \ldots & \ldots & 0 & -y & 0
\end{pmatrix}
\]

Proposition 5.2. \( Pf_{n-1}(H_n) \) is a Gorenstein ideal of height 3 in \( R \).

Proof. An easy computation shows that \( Pf_{n-1}(H_n) \) contains powers of \( x, y, z \). Thus height \( (Pf_{n-1}(H_n)) = \) depth \( (Pf_{n-1}(H_n)) = 3 \), and an application of part 1 of Theorem 4.1 finishes the proof.
